

Microservices Architecture Guide

Department/Category: Engineering

Synthetic demonstration document for the Infosys GPT project. This material is fictional and should not be treated as an official Infosys policy, guide, manual, sales asset, or SOP.

Purpose

This synthetic enterprise reference document describes recommended practices for designing and operating microservices in a demonstration environment. It is demo material and is not an official company policy.

Service Boundaries

Each microservice should have a clearly defined business capability and an independently deployable responsibility. Teams should avoid creating services solely to split a monolith into arbitrary technical layers.

API Standards

REST APIs should use resource-oriented paths, consistent HTTP status codes, documented request and response schemas, and explicit versioning for breaking changes.

Observability

Production services should emit structured application logs, health indicators, and request metrics. Correlation identifiers should be propagated across service-to-service calls.

Deployment

Changes should pass automated tests before deployment. Production releases should use an approved deployment process and provide a rollback path.

Security

Services should authenticate requests, enforce authorization at service boundaries, validate input, and avoid storing secrets directly in source code.
